# Role of Perfectionism, Self-Compassion, and Cultural Values on Help-Seeking Attitudes of Asian American College Students

# Bau, K. E., Grigg, M. R., Law, J. P., Ryu, S. H., Steele, J. M., Kim, P. Y.

We examined the impact of self-compassion in positive help-seeking attitudes and the effects of perfectionistic self-presentation related to help-seeking attitudes in a sample of Asian American college students at two Pacific Northwest 4-year institutions (N = 101). We first predicted that perfectionistic self-presentation would be related to more unfavorable help-seeking attitudes (Hypothesis 1). Second, we predicted that self-compassion perfectionistic self-presentation would be related to more favorable help-seeking attitudes (Hypothesis 2). We also explored the impact of cultural elements (emotional self-control, family recognition through achievement) as correlates of help-seeking attitudes. Our results indicated that non-disclosure of imperfection and emotional self-control were significantly correlated with unfavorable help-seeking attitudes. Unwillingness to talk about imperfections and cultural values of emotional restraint might act as barriers to seeking psychological services for Asian American college students.

# Introduction

Asian American college students tend to underutilize mental health services et al., 2005) and might have more unfavorable attitudes toward seeking professi psychological help (Masuda et al., 2009). To address this mental health disparity, w examined three correlates of help-seeking attitudes among Asian American c students. Data collection is currently ongoing, but in this poster we present preliminary analysis based on 101 Asian American participants.

# Perfectionism

- Factors such as the rise of social media and increased competition have led to elevated levels of perfectionism among young people in recent years (Curran & 2017). The desire to appear perfect has been found to be correlated with negative mental health outcomes (Shannon, 2018).
- Perfectionistic Self-Presentation refers to a dimension of perfectionism involvi impression management that seeks to display perfection in social contexts. 7 facets involved in perfectionistic self-presentation are perfectionistic selfpromotion, nondisplay of imperfection, and nondisclosure of imperfection (Hew al., 2003).
- Perfectionistic self-presentation involves a demonstration of perfectionistic behavior and can be seen as maladaptive (Hewitt et al., 2003).
- Past research on perfectionism indicates that a perfectionistic front could help mask psychological distress in order to avoid mental illness stigma (Shannon, 20
- We predicted that high levels of perfectionistic self-presentation will be correl to more unfavorable help-seeking attitudes.

## Self Compassion

- Self-compassion is defined as the ability to be kind to oneself, accept imperfe and hold a balanced perspective of one's own suffering (Raes et al., 2011).
- Having compassion for oneself allows for one's ability to see their success an failings clearly, and often involves desiring good health and well-being for one (Neff, 2003).
- Self-compassion has been shown to be a protective factor in psychological dis in its ability to promote emotional resilience, resulting in lower levels of depre and anxiety (Raes et al., 2011).
- We predicted that high levels of self-compassion would be related to positive seeking attitudes among Asian American individuals.

# **Asian Cultural Values**

- *Cultural values*, defined as what people view as attractive or desirable, can b unique to Asian American individuals (Smith & Bond, 1994).
- B. S. K. Kim et al. (2005) empirically identified key cultural values among Asi Americans: collectivism, conformity to norms, emotional self-control, family recognition through achievement, and humility.
- In our study, we examined emotional self-control and family recognition through achievement as a correlate of help-seeking attitudes.
- Emotional self-control: One's adherence to cultural values can determine how manifests psychological problems and expresses emotions (B. S. K. Kim et al., 2005 Adherence to emotional self-control has found to be correlated with negative seeking attitudes (P. Y. Kim & Lee, 2014).
- Family recognition through achievement: Although this variable has not been found to be significantly related to help-seeking attitudes, given the other variables in the study (e.g., perfectionism), we reasoned that it might be important to include this cultural value in our study.

## Results

sure of imperfection was negatively correlated with attitudes towards ofessional psychological help (r = -.24, p < .05), therefore our 1 was supported.

assion was negatively correlated with all dimensions of perfectionistic itation, including perfectionistic self-promotion (r = -.24, p < .01), y of imperfection (r = -.47, p < .01), and non-disclosure of on (r = -.40, p < .01).

self-control was negatively correlated with attitudes towards seeking al psychological help (r = -.35, p < .01) and self-compassion (r = -.35) and (r = -.35) and

## Discussion

indicated a significant relationship between non-disclosure of on and unfavorable help-seeking attitudes. This finding may suggest ological help-seeking environments may not align with how a person resent themselves in terms for acknowledging shortcomings nor conducive for preventing the disclosure of imperfections.

y, consistent with prior studies (e.g., P. Y. Kim & Kendall, 2015; P. Y. Kim & Lee, ional self-control was also related to unfavorable help-seeking ndicating that individuals who express high emotional regulation are to see professional psychological help as beneficial and are therefore to engage in help-seeking behaviors. Further research is needed to is relationship is explained by aversive attitudes towards settings e emotional vulnerability or rather an expression of self-sufficiency on of emotions.

did not show a significant relationship self-compassion was not positive help-seeking attitudes, however there were several correlations between self-compassion and perfectionistic selfon. Overall, trends showed that individuals with lower selfn scores were more likely to express perfectionistic self-promotion, non-presentation of imperfection, and emotional self-control. of our study inform psychological practice in ways that involve the knowledge the role of perfectionistic self-presentation in therapeutic s well as investigating how familial and cultural influences may fectionistic tendencies. Models of therapy oriented around self-compassion can be particularly helpful to individuals who rfectionism, as Mehr and Adams (2016) study depicts selfn as a mediator between maladaptive perfectionism and depressive
